

To the Commissioner of Patents & Trademarks:

This is an application for Letters Patent of the United States of America on an invention
entitled

DUAL-ARM LINEAR SLIDE MECHANISM FOR AN EXTENDABLE REARVIEW
MIRROR FOR VEHICLES

by John S. McPherson of Perkasio, Pennsylvania and Keith Fitzgerald of Coopersburg,
Pennsylvania, both citizens of the United States of America.

DUAL-ARM LINEAR SLIDE MECHANISM FOR AN EXTENDABLE
REARVIEW MIRROR FOR VEHICLES

1 RELATED APPLICATIONS

2 The present application is a continuation-in-part of co-pending patent application serial
3 number 10/092,580 filed March 8, 2002 for "Linear Slide Mechanism for an Extendable Rearview
4 Mirror for Vehicles," which claimed priority from provisional application serial number
5 60/283,753 filed on April 16, 2001, entitled "Linear Slide Mechanism for an Extendable Rearview
6 Mirror for Vehicles."

7 FIELD OF THE INVENTION

8 The present invention relates to a rearview mirror for a vehicle which is extendable toward
9 or away from the vehicle laterally to selectively provide different viewing positions as desired, for
10 example when the vehicle is towing a trailer or the like.

11 BACKGROUND OF THE INVENTION

12 It is known to provide vehicles with extendable rearview mirrors which extend selectively
13 from the vehicle body along a support arm which extends laterally from the body of the vehicle.
14 This type of extendable mirror is shown for example in U.S. Patent 5,572,376 issued to Pace.
15 The Pace mirror further includes a rack gear drive and a flexible boot which provides a cover
16 between the vehicle and the motor housing to protect portions of the apparatus from exposure. A
17 problem with this prior art device, however, is that the slidable components of the sub-assembly
18 and support arm produce wear of the parts, thus creating undesirable movement in the slide
19 assembly which produces excessive vibration in the mirror assembly resulting in poor vision
20 through the mirror. It is known to use plate springs such as shown in the above-captioned U.S.

1 Patent to Pace to take up clearances between slide components of the extension arm mechanism
2 however, because of the limited space between these parts, the practical use of this type of spring
3 provides a spring force which is relatively weak in relation to the reaction forces created by the
4 mass of the mirror sub-components.

5 Another extendable rearview mirror for a vehicle is disclosed in U.S. Patent 6,116,743
6 issued to Hock. The mirror assembly of the Hock device includes a bracket which is slidable
7 around a support arm and includes internal spring means for taking up the gap between the outer
8 surface of the support arm and the inner surface of the bracket. This device is a complex
9 assembly of many small parts including screws and other fasteners. U.S. Patent 5,969,890 issued
10 to Whitehead shows an extendable mirror which slides along longitudinal rails located on the
11 outside of the mirror housing. Hence the rails are not protected from the adverse elements of the
12 weather.

13 There is therefore a need in the art for an extendable rearview mirror support mechanism
14 which is resistant to wear and which remains extremely stable and vibration-resistant throughout
15 the entire stroke of its motion. It is further desired to provide a mechanism which is easily
16 assembled to allow high volume manufacturing. For yet further economy of manufacture there is
17 a need to provide a "no-tool assembly" of parts.

18 SUMMARY OF THE INVENTION

19 In order to solve the needs in the art explained above, the present invention provides an
20 extendable rearview mirror for a vehicle which provides a spring-clamped slide mechanism that
21 ensures a zero tolerance fit between sliding components to avoid vibration. It further includes
22 bearing members between the sliding components to reduce friction and provide a consistent

1 reaction force to ensure smooth operation of the actuator mechanism. This type of mirror is
2 particularly useful in situations where the vehicle is towing something behind it and enhanced
3 rearward vision is provided by positioning the rearview mirror to its fully-extended position.

4 The superior functional characteristics of the present invention are provided by a unique
5 support bar clamp mechanism which slidably affixes the rearview mirror housing and other
6 components of the rearview mirror assembly to the support arm. The sliding movement is
7 achieved with accurate slidable engagement of the mirror assembly along the support arm through
8 the full extent of its longitudinal movement. This structure includes unique upper and lower V-
9 shaped guide rails which face opposing V-shaped guide rails on the mounting bracket assembly.
10 Rod-like bearing means are interposed between the bracket guide rails and the support arm guide
11 rails to engage the mounting bracket and the support arm against movement in any direction
12 except along the longitudinal axis of the support arm.

13 To achieve a sufficient amount of clamp force, the bracket assembly includes a cantilever
14 clamp jaw which also includes the lower bracket guide rail. The clamp jaw is pivotal about a
15 fulcrum and is biased toward clamping engagement with the support arm by spring means which is
16 operative between a mirror sub-assembly mounting bracket and the lever arm of the clamp jaw
17 which extends to the opposite side of the mounting bracket. Because of the shape of modern
18 rearview mirror housings that is dictated by aesthetic considerations, there is a large void in the
19 housing behind the mirror assembly mounting bracket. Since the spring means of the present
20 invention is behind the bracket and positioned in this void, a single, large spring with a high spring
21 force can be used. This high spring force provided by the present invention contributes
22 significantly to the superior rigidity of the present design compared to the prior art. Support arm

1 clamp force may be further increased by the mechanical leverage provided by the clamp jaw lever
2 arm.

3 In one embodiment of the invention the bearing rods are composed of an ablatable
4 material which leaves deposits on the support arm guide rails as it is used. These material
5 deposits act as a filler to smooth over surface irregularities of the guide rails which may be present
6 if inexpensive casting methods are used to form the rails. In this way, the respective bearing
7 surfaces are increased in area as the bearings “wear in”. This occurs rapidly since the unit surface
8 pressure between the bearing material and the guide rails is initially very high due to the very small
9 point of contact between the cylindrical outer surface of the rod and the flat surfaces of the V-
10 shaped rails. When the slide mechanism is operated, the material of the bearing rods is quickly
11 removed from the rods and deposited along the surface of the support arm rails until a point of
12 equilibrium is reached between the surface friction and the increase in bearing surface area. Once
13 this wear-in point is reached, a consistent and low coefficient of surface friction is maintained.

14 More specifically, the applicants have invented an extendable rearview mirror assembly for
15 a vehicle which includes a rotatable support arm for attachment to a vehicle body. A mirror
16 assembly is mounted on the support arm and includes a bracket and a surrounding housing affixed
17 thereto. A mirror sub-assembly including a mirror glass, support plate, and motor-driven
18 positioning means is affixed to a first side of the bracket and lies within the housing. The
19 assembly includes clamp means with jaws on the bracket for slidably affixing the bracket to the
20 support arm. A first clamp jaw is adjacent the top of the housing and stationary with respect to
21 the bracket and engages a first guide rail located along a top of the support arm. A second
22 movable clamp jaw is adjacent the bottom of the housing and includes pivot means to forceably

engage a second guide rail located along a bottom of the support arm. The first and second jaws define a substantially vertical clamping plane between them which lies along the first side of the bracket. The mirror assembly also includes a first bearing means interposed between the first jaw and first guide rail and a second bearing means interposed between the second jaw and the second guide rail. Both bearing means are elongate, rod-shaped members composed of solid PTFE, a substantially ablatable material, such that initial operation of the slide mechanism causes the bearing means to deposit friction-reducing material upon the surfaces of the guide rails. The first and second jaws each include a guide rail and face opposite their respective support arm guide rails. All guide rails further include surfaces which have a V-shaped cross-section. The movable clamp jaw includes force-applying spring means urging the second jaw in a direction of clamping and is movable to a point of release where the bracket is laterally releasable from the support arm. The second clamp jaw moves by way of a lever arm having a first end which engages the coil-type compression spring means and extends to an opposite side of the bracket. The bracket has a fulcrum about which the lever arm pivots. The fulcrum is on a bottom support plate of the bracket which holds the spring and the second jaw in their operative positions solely by the co-mutual compression of engaged parts. The spring operates between the end of the lever arm and an abutment both being located on the opposite side of the bracket. The aggregate center of mass of all components is adjacent the plane of clamping.

The assembly also comprises a support arm having a mounting bracket affixed to it in slidable engagement. The clamp means on the bracket includes two jaws each engaging top and bottom edges of the support arm respectively, the clamp means including a movable jaw which pivots on a lever arm extending from the bracket such that the movable jaw forceably engages a

1 bearing surface along one of the edges of the support arm. The bracket is slidably affixed to the
2 support arm on only one side such that when the jaw is moved to a point of release, the jaws of
3 the clamp means are laterally releasable from the edges of the support arm.

4 The low friction of the slide assembly of the present invention is beneficial in that it
5 requires a lower actuator force which contributes to the lower power consumption, low noise,
6 and longer life of the actuator motor and drive system which may be any suitable screw or gear-
7 drive system known in the art. The invention achieves all of these attributes while rigidly
8 restricting movement along all axes of motion except the longitudinal axis of the support arm.
9 The rigidity of the system is further enhanced by employing guide rails which are vertically spaced
10 a greater distance apart than other known internal slide assemblies. This provides wide-track
11 stability in the vertical plane and thus torsional vibration is mitigated and stable reflected vision
12 through the mirror plate is achieved. Other objects and advantages of the present invention will
13 be apparent from the following drawings and description of the preferred embodiment.

14 BRIEF DESCRIPTION OF THE DRAWINGS

15 Figure 1 shows an exploded perspective view of a rearview mirror unit which employs the
16 slide assembly of the present invention.

17 Figure 2 is a partial view of Figure 1 showing the main components representing the slide
18 mechanism of the present invention.

19 Figure 3 is a side sectional view of the completed assembly of parts shown in Figure 1.

20 Figure 4 is a top rear isometric view of the slide assembly of the present invention.

21 Figures 5a and 5b are side sectional views of the bearing and guide rail points of
22 engagement showing the initial surface contact points before and after break-in respectively.

Figure 6 is a rear partially-sectioned cut-away view of an alternate embodiment of the invention.

Figure 7 is a right side sectional view taken from Figure 6 as indicated in that figure.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to Figure 1, an exploded assembly view of the present invention including all major components of the rearview mirror are shown. A mirror sub-assembly 11 comprises a mirror glass support and motor driven positioning elements fitted to the bracket assembly 13 which includes support arm 17 that is attached to a vehicle body bracket (not shown) preferably by rotatable mount 10 at one end of the arm. The bracket of the slide assembly is affixed to housing 15 that includes an aperture 16 through which the support arm 17 extends. The assembly may further include an extendable-contractible flexible boot 19 to protect the support arm from exposure.

Referring now to Figure 2, the preferred embodiment of the slide mechanism of the present invention includes bearing rods 19 which are interposed between the V-shaped guide rails of support arm 5 and complementary opposing V-shaped rails on the bracket assembly. The bracket assembly includes bracket 3 and clamp jaw 7 which is biased toward the upper guide rail of the bracket by spring means 12 which supplies a spring force through a lever arm of the clamp jaw that extends to the opposite side of the bracket. The bracket 3 is affixed to the mirror housing 1 by suitable attachment means such as screws 22.

Referring now to Figure 3, a side sectional view of the complete assembly of components shown in Figure 1, is depicted. Bracket assembly 13 carries the mirror sub-assembly 11 that includes the mirror glass, a support plate, and motor driven positioning means. The cantilever

1 clamp jaw 7 pivots upon fulcrum 8 to forceably clamp the support arm 17 into slidable
2 engagement with the bracket assembly. The fulcrum 8 is located along a portion of the bracket
3 bottom support plate 35. A lever arm 9 of the clamp jaw extends to the opposite side of the
4 bracket assembly and is forced downward by compression coil spring 12 that operates between
5 the end of clamp jaw lever arm 9 and bracket spring abutment 32. Bearing rods 19 are interposed
6 between opposing V-shaped guide rails which laterally traverse the top and bottom edges of both
7 the bracket assembly and the support arm. By this construction, the support arm rails are self-
8 centering between the bracket rails. Also, it will be readily understood from the mechanical
9 relations shown in Figure 3 that movement of the support arm with regard to the bracket assembly
10 will be rigidly restricted along all axes of motion except the longitudinal axis of the support arm.
11 It will further be observed that spring means 12 will alone retain the assembly of the parts without
12 the need for any other fastening means, all parts being held together in interlocking engagement
13 by the spring force of spring 12. This provides greatly reduced assembly time and fewer parts.

14 The guide rails are preferably coplanar in the vertical plane therefore providing great
15 rigidity against torsion in the vertical plane. Furthermore, the bracket and support arm are
16 preferably C-shaped so that the center mass of the mirror sub-assembly is close to the vertical
17 plane defined by the guide rails and the support arm. The forward extending (relative to the
18 vehicle) lever arm and spring also aid in advantageously locating the center of mass of the mirror
19 sub-assembly proximate to the guide rail plane. This further adds to the rigidity of the assembly
20 by decreasing the torsional reaction force moment about the support arm axis created by vertical
21 accelerations.

22 Referring now to Figure 4, the clamp jaw lever arm and spring means is clearly depicted.

1 Bracket 33 includes a bottom support plate 35 which captively receives a projection of the
2 cantilever clamp jaw to establish a fulcrum and point of rotation. Spring means 12 operates
3 between the end of the clamp jaw lever arm 36 and an abutment 32. Support arm 17 includes
4 upper and lower V-shaped guide rails 38 and 39 respectively. Since coil spring 12 is not located
5 directly between the sliding parts, it may be a large and powerful spring which can supply the
6 desired amount of rigidity to the slide assembly.

7 Referring now to Figures 5a and 5b, before and after side sectional views of the bearing
8 rod and guide rail contact points are shown for the upper support arm guide rail 38 and opposing
9 upper bracket guide rail 20. As depicted in these illustrations, the bearing rods 19 deposit some
10 of their material 34 along the surface of the guide rails 38 of the support arm as the bearing rods
11 19 wear in. Initially, frictional points of contact are along lines on the surface of the bearing rods.
12 As the slide mechanism wears in, the areas of contact 36 become planar (i.e. flat surfaces) and
13 thus contact area is greatly increased after break-in. This reduces the coefficient of friction
14 between the sliding parts and provides a uniform contact surface area between the sliding parts at
15 all points along the stroke of the bracket assembly. The increase in contact surface area also
16 contributes to the rigidity of the mechanical engagement between the parts. Unwanted vibration
17 is further mitigated by the use of a soft, ablative bearing material, of the preferred type. Such a
18 material is solid Teflon® PFTE of the general type.

19 Referring now to Figures 6 and 7, an alternate embodiment of the present invention is
20 shown. In this embodiment, the support arm includes a void which extends to the pivot end of the
21 support arm forming separate top and bottom legs 50 and 51. Referring to Figure 6, as in the
22 previous embodiment, the remainder of the support arm structure within the mirror housing

1 includes clamp means **40** which includes a bracket affixed to the mirror assembly. The assembly is
2 driven by motor means **41** and pinion **42** which engages rack **43**. Thus, the housing and mirror
3 assembly **44** may be reciprocally driven between extended and retracted positions A and B with
4 movement therebetween shown by the arrows in this figure. The end of each support arm leg
5 includes pivot joint **45** with detent means (not shown) for the usual hinged attachment to the
6 mirror mount casting **46** which is in turn affixed to the side of the vehicle. Any suitable detent
7 mechanism may be employed which cooperates with the mirror mount **46** which is affixed to the
8 vehicle and the flanges at the ends of the support arm legs which are hingably affixed to the
9 mount. Telescoping covers encase both of the support arm legs including members **48** and **49**
10 which surround the top leg and members **52** and **53** which surround the bottom leg. Providing a
11 void in the support arm reduces the frontal area and thus the wind resistance of the support arm
12 structure. It further permits individual telescoping covers to be utilized, one for each leg extension
13 as shown in this figure.

14 Referring now to Figure 7, the components within the mirror housing of this alternate
15 embodiment are substantially the same as those shown in the embodiment of Figures 1-5a except
16 for dimensional changes. The mirror assembly and housing **44** is affixed to traveling clamp
17 assembly **40** which by pressure of spring means **47** forceably engages opposing top and bottom
18 edges of the support arm structure by means of complementary V-grooved guiderails and
19 intermediate bearing rods **48** and **49**. The housing assembly is driven by gear motor **41** that drives
20 pinion **42** which is engaged with toothed rack member **43**. As shown in this figure, the upper and
21 lower support arm legs **50** and **51** reside within telescoping members **48** and **49** at the top and
22 telescoping members **52** and **53** at the bottom all having a substantially circular cross section.

1 This alternate embodiment allows for locating the support arm guiderails a greater distance apart
2 which provides greater torque resistance between the vehicle and the mirror assembly while
3 providing low wind resistance and an aesthetically acceptable appearance. The telescoping
4 guiderail covers may be composed of a wide range of materials since they are not load-bearing but
5 merely utilized to protect the guiderails from the outside environment.

6 It will be understood to those of skill in the art that there may be many modifications and
7 adaptations of the invention other than those specifically described from the foregoing preferred
8 embodiment and alternate embodiments. However, the present invention should be limited in
9 scope only by the following claims and their legal equivalents.
